# VUD: Flanged through valve, PN 6

## How energy efficiency is improved

For efficient use in continuous control systems.

## Areas of application

Continuous control of cold and hot water and air in closed networks<sup>1)</sup> and flow temperature control in heating systems. Water quality as per VDI 2035. Together with actuators AVM 105, AVM 115, AVM 124/125, AVF 124/125, AVM 234S, AVF 234S and AVN 224S as regulating unit.

## Features

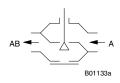

- Nominal pressure 6 bar
- Control valve, contains no silicone grease; painted black
- Nominal diameters DN15 to DN100
- · Equal percentage characteristic, adjustable with SUT actuators to linear or quadratic
- With the spindle retracted, the valve is closed
- Closing procedure: against the pressure DN15 to DN100 or with the pressure DN15 to DN50

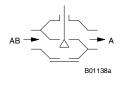

## **Technical description**

- Valve with flange connection as per EN 1092-2, Form B, raised face
- Valve body and seat made of cast iron
- Stainless steel spindle
- Nominal diameter DN15 to DN50 cones in brass with glass-fibre reinforced PTFE sealing ring
- Nominal diameter DN65 to DN100 cones in brass, with metal-to-metal seal
- Stuffing box made of brass with wiper ring and double O-ring seal in EPDM

#### Function

The valve can be controlled into any desired intermediate position by means of an electrical drive. If the valve stem is pulled out, the control passage of the valve is closed. Valves with nominal diameters DN 15 to DN 50 may be deployed using closing procedures 'against the pressure' and 'with the pressure'. Nominal diameters DN 65 to DN 100 may only be used with a closing procedure 'against the pressure'. The direction of flow marked on the valve must be observed, or covered with a sticker if used 'with the pressure'. Parameters related to flow mechanics conform to EN 60534.

#### Description

The key features of these control valves are their high reliability and precision, and they make a major contribution towards environment-friendly control. They meet demanding requirements including quick-close functions, coping with differential pressures, controlling the medium temperature and providing a shut-off function - and all this is achieved with a low noise level.

An automatic and fixed connection is made between the valve stem and the drive shaft. The cone (which is made of brass) controls an equal-percentage flow in the control passage. The tightness of this valve is guaranteed by the seat which is machined in the body.

The stuffing box is maintenance-free; it consists of a brass body, 2 O-rings, a wiper ring and the grease reserve. This is free of silicone grease and no silicone oil must be used for the stem.

#### **Engineering and fitting notes**

The valves are combined with valve drives without spring return action, or valve drives with spring return action. The drive is placed directly on top of the valve and is fixed either with a nut or with screws. The connection between the drive and the valve stem is made automatically. When the plant is operated for the first time, the drive moves out and the lock closes automatically once it has reached the lower valve seat. The valve stroke is also detected by the drive and no further adjustments are required. This means that the force on the seat is always equal and the lowest leakage rate is always guaranteed. With the SUT drives, the characteristic can be changed over to linear or quadratic as desired. For the combination AVM 105S with DN50 F200 it is not possible to change the character from linear to equal-percentage.

#### Installation position

The final control element can be installed in any desired position, but the an installed position facing downwards is not recommended. Condensate and water drips etc. must be prevented from penetrating into the drive. With nominal diameters DN 65 to DN 100 in a horizontal installed position and in relation to the valve stem, the permitted maximum drive (or other) weight is 25 kg unless a support is provided by the customer or others. When fitting the drive onto the valve, you must make sure that the cone is not rotated on the seat (this would damage the sealing surface). If the valve is insulated, the insulation must only extend as far as the connecting clip of the drive.

#### Applications with steam

The valves must not be used for applications involving steam.

#### Applications with water

To ensure that impurities in the water (such as welding beads or particles of rust, etc.) are retained and the stem seal is not damaged, it is advisable to install collective filters, e.g. for each storey or pipe run. Water quality requirements conform to VDI 2035.

If an additional medium is used, the compatibility of the materials must be clarified with the manufacturer of the medium. The Material Table shown below can be used for this purpose. If glycol is used, we recommend that a concentration of between 20% and 55% should be selected.

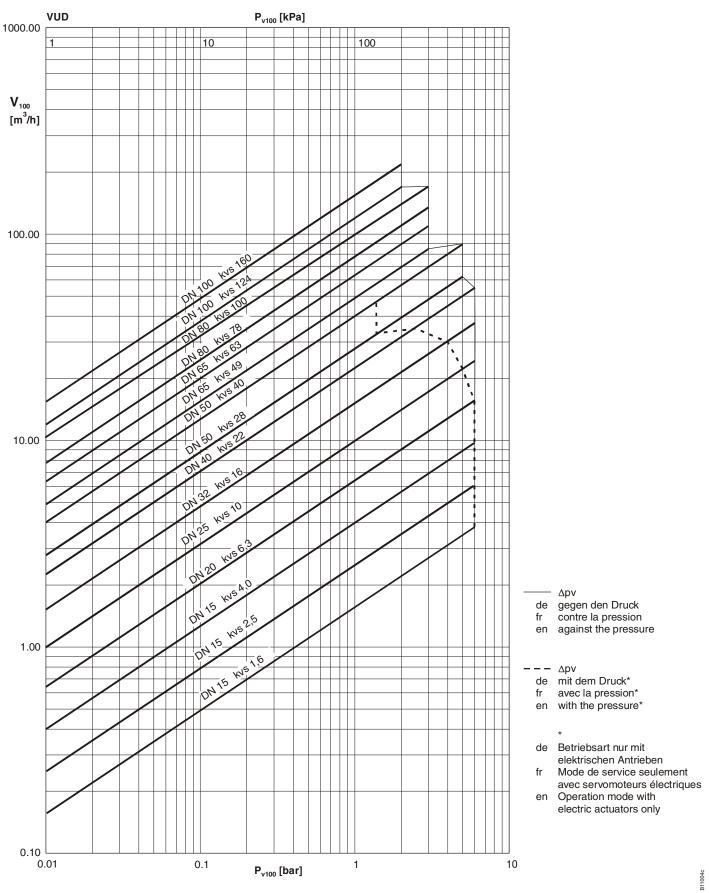

The valves are not suitable for drinking water or Ex zones.

#### Other notes concerning hydraulics and noises in systems

The valves can be used in a low-noise environment. To avoid noises, the pressure differences  $\Delta p_{max}$  listed below should not be exceeded.

The close/off pressure values which are also listed represent the maximum pressures at which the drive can still use its own force to move the valve. It should be pointed out here that if these pressures are used and the pressure difference  $\Delta p_{max}$  is exceeded, the valve may sustain damage due to cavitation and erosion. In case of a spring return function, the stated  $\Delta p_s$  values also represent the permitted differential pressure up to which the drive guarantees closure of the valve in case of an incident. As this is a quick-close function with 'fast' passage through the stroke (by means of the spring), this value may exceed  $\Delta p_{max}$ .

#### Amplified information on pressure difference definitions

#### ∆pv:

Maximum permitted pressure difference over the valve for every position of the stroke, limited by noise level and erosion.

This parameter specifically characterises the hydraulic behaviour of the valve as an element through which a flow passes. Monitoring of cavitation and erosion, and the associated development of noise, will improve the valve's lifetime as well as its usability.

#### $\Delta \mathbf{p}$ max:

Maximum permitted pressure difference over the valve at which the drive can reliably open and close the valve.

The following are taken into account: static pressure and influences related to flow mechanics. Faultless performance of the stroke and tightness are guaranteed with this value, and in no case is valve value  $\Delta p_v$  exceeded.

#### ∆ps:

Maximum permitted pressure difference over the valve in case of a fault (such as a voltage failure, excessive increase in temperature and pressure, and pipe break) at which the drive can close the valve tightly and can hold the full operating pressure against atmospheric pressure if need be. As this is a quick-close function with a 'fast' performance of the stroke,  $\Delta p_s$  may be greater than  $\Delta p_{max}$  or  $\Delta p_v$ . The disruptive influences arising here in connection with flow mechanics are quickly passed through, and are of secondary importance in this functioning mode.

For three-way valves, the values only apply to the control passage.

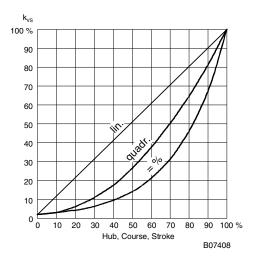

#### ∆pstat:

Pipe pressure upstream of the valve. Essentially corresponds to the dead pressure with the pump switched off, caused (for example) by the fluid level in the system, increase in pressure due to the pressure tank, steam pressure, etc.

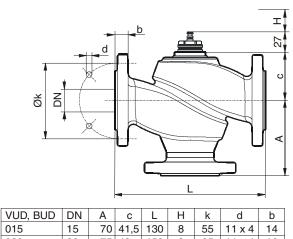

For valves which close with the pressure, the static pressure added to the pump pressure must be used for this purpose.

## Characteristic for drives with a positioner
